

Figure 1: Sela Creek licence area, soil sample locations and artisanal workings. Puma is located 2.4 km southeast from Jons Pit and was the subject of infill soil sampling in 2013. Samples from the Panther area and north of Cambior have not been submitted for assay.

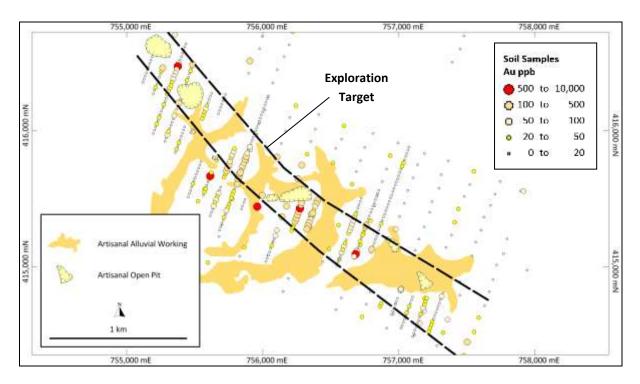

Figure 2: Gold in soil results, Puma Prospect. The soil anomaly occurs over a strike length of >3 km and is open along strike. Samples greater than 100 ppb gold are considered highly anomalous. The soil anomaly is between 200 and 400 meters wide and has been exploited in parts by artisanal open pits.

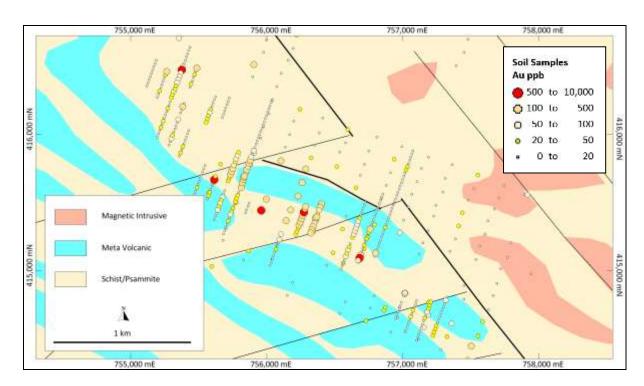

Figure 3: Gold in soil results with geology inferred from airborne magnetic data, Puma Prospect. Note the gold in soil anomaly is located at the contact between iron-rich metavolcanic rocks and schist.
